Solve for x: $3(2x-4)+5=2x+9$

To solve for x, we should first simplify the left side of the equation. What is the correct way to expand the term $3(2x - 4)$?

$6x - 12$

That is correct. The equation now looks like this: $6x - 12 + 5 = 2x + 9$. What is the simplified form of the equation after combining the constant terms on the left side?

$6x - 7 = 2x + 9$

That is correct. The equation is now $6x - 7 = 2x + 9$. What is the next logical step to group the x-terms on the left side?

Subtract $2x$ from both sides to get $4x - 7 = 9$

 Start a new problem

terms on the left side.

Subtract $2x$ from both sides to get $4x - 7 = 9$ That is correct. The equation is now $4x - 7 = 9$. What is the next step to isolate the term with x ?

Add 7 to both sides

That is correct. The equation is now $4x = 16$. What is the final step to solve for x ?

Divide both sides by 4

That is correct. Dividing both sides of $4x = 16$ by 4 will isolate x . What is the resulting value? $x = 4$ 

That is correct. To solve $3(2x-4)+5=2x+9$, you first expanded the parentheses to get $6x-12+5=2x+9$, then simplified the constants to $6x-7=2x+9$. You then moved the x -terms to one side and the constants to the other, resulting in $4x=16$, and finally divided by 4 to find $x=4$.
